

# Installing Python: Linux

This lesson is a tutorial on how to install Python in a Linux environment.

## We'll cover the following

- Python in Linux
  - Checking the Version
    - Python2
    - Python3
- 1. Using the PPA Repository
- 2. Using the Official Site (Advanced)
- 3. Using Anaconda (Simple)

Installation is a slightly different process for every operating system. This lesson is a guide for installing Python on Linux. You can move on to the next lesson if this isn't relevant to you.

## Python in Linux #

Many Linux distributions come with a pre-installed version of Python. Older distributions can have Python 2.7, whereas the newer ones may come equipped with the latest version. However, this is not a guarantee.

Below, we'll highlight the different approaches for ensuring that our Linux machine has the latest Python installed. For simplicity, we'll show the process for **Ubuntu**.

## Checking the Version #

The first step should always be to check if there is a version of Python and/or Python3 already installed. For this, simply have to go to the terminal and enter the following commands:

Python2 #

```
python --version
```

## Python3 #

```
python3 --version
```

If our system does not have a distribution for Python3, we can move on with the installation.

## 1. Using the PPA Repository #

This is a fast way of setting up Python on our machine. It also ensures automatic version updates in the future.

We'll be using the third-party repository called PPA. For this, we'll run the following commands to install all the required packages:

```
sudo apt update
sudo apt install software-properties-common
sudo add-apt-repository ppa:deadsnakes/ppa
```

All that's left is to download the latest version of Python3 which is Python 3.7:

```
sudo apt update
sudo apt install python3.7
```

And we're good to go! We can confirm the version using `python3.7 --version`.

## 2. Using the Official Site (Advanced) #

Visit the [official Python download page](#) and select the latest version:

Select the **XZ compressed source tarball** and let the download complete.

In the meantime, we will install the packages required for Python using the following commands line by line:

```
sudo apt update

sudo apt install build-essential zlib1g-dev libncurses5-dev libgdbm-dev libnss3-dev libssl-dev lib
```

Now, copy the downloaded Python tarball into the **usr/src** directory and move there. If the tarball is in the **Downloads** folder, this should work:

```
sudo cp ~/Downloads/Python-3.7.3.tar.xz /usr/src
cd /usr/src
```

Let's unpack the tarball and move into its directory:

```
tar -xf Python-3.7.3.tar.xz
cd Python-3.7.3
```

Next, we have to set up the configuration for the installation. Finally, we just have to use the **make altinstall** command to install Python. Enter these commands:

```
./configure --enable-optimizations
sudo make altinstall
```

And there we have it! Python3 is ready for use on our Machine. We can check the version using **python3.7 --version**.

### 3. Using Anaconda (Simple) #

Anaconda is a very popular open source data science platform which comes equipped with Python3 out of the box. Furthermore, many Python3 libraries and packages are already pre-installed.

This is definitely the best approach for beginners who are new to shell and terminal commands.

The setup is fairly simple. Visit the [official download page](#) and select the installer for Linux (both graphical and command-line installers are available).

After installation, we can simply type `python` in the terminal to run Python. This will show us the version which we're running and shift us to the Python environment. Don't worry about the rest for now. Exit the Python shell using `quit()`.

These are all the different ways we can install Python3 on our Linux machine. Hopefully, everything went smoothly. If you have any questions, do reach out to us!

In the next lesson, we'll learn how to set up Python for Windows.
